Approximately 900- and 400-nm-thick BaSi₂ epitaxial films were grown on Si(111) and Si(001) substrates, respectively, by molecular beam epitaxy, and their photoresponse properties were compared at room temperature. When the bias voltage V_{bias} applied between the 1.5-mm-spacing stripe-shaped electrodes on the BaSi₂ surfaces increased, photocurrents were clearly observed for photon energies greater than the band gap for both samples. However, the photoresponsivity for BaSi₂ on Si(001) was more than 8 times larger than that for BaSi₂ on Si(111); reaching approximately 50 and 5 mA/W at 1.6 eV, respectively, when V_{bias} was 1.0 V. This is attributed to the difference in the grain size of BaSi₂ films confirmed by plan-view transmission electron microscopy.

1. Introduction

It is important for solar cell materials to have a large absorption coefficient and a suitable band gap that matches the solar spectrum to yield high conversion efficiency. Among such materials, we have focused on semiconducting orthorhombic BaSi₂. The band gap of BaSi₂ is approximately 1.3 eV and can be increased up to 1.4 eV in Ba_{1-x}Sr_xSi₂ [1,2], which matches the ideal solar spectrum much better than crystalline Si. In addition, BaSi₂ has a very large absorption coefficient α of approximately $3 \times 10^4 \text{ cm}^{-1}$ at 1.5 eV [2]. A large value of α and expansion of the band gap in Ba_{1-x}Sr_xSi₂ were theoretically expected [3,4]. BaSi₂ can be grown epitaxially on a Si(111) substrate with the orientation alignment of BaSi₂(100)//Si(111), with a small lattice mismatch of 1.0% for BaSi₂[010]//Si[112] [5]. Therefore, lots of studies have been done on BaSi₂ epitaxial films grown on Si(111) by molecular beam epitaxy (MBE). Recently, we have achieved large photoresponsivity in undoped *n*-type BaSi₂ epitaxial layers on Si(111) and polycrystalline BaSi₂ layers on (111)-oriented polycrystalline Si layers on SiO₂ [6-8]. With respect to the lattice mismatch, we have considered that the (111) facet of a Si substrate is best for BaSi₂ growth, although the grain size of BaSi₂ is as small as approximately 0.2 μm [9]. This is because of three epitaxial variants, due

to the sixfold symmetry of Si(111) [10], rotating around each other by 120° in the surface normal. Many grain boundaries and other defects in a film would deteriorate the optical and electrical properties. Thus, it is important to increase the grain size of BaSi₂ films. Note that *a*-axis oriented BaSi₂ was surprisingly grown on the Si(001) substrate, despite the large lattice mismatch of 0.1% for BaSi₂[001]//Si[110] and 12.5% for BaSi₂[010]//Si[110] [5]. Very recently, we found that the grain size of *a*-axis-oriented BaSi₂ epitaxial layers on Si(001) is more than 1 μm , much larger than that on Si(111) [11]. However, we have not yet measured photoresponse properties of BaSi₂ epitaxial films on Si(001). In this paper, we aimed to compare the photoresponsivity of BaSi₂ grown on Si(001) with that on Si(001), already reported in Ref. [7].

2. Experimental

An ion-pumped MBE system equipped with standard Knudsen cells for Ba and Sb, and an electron-beam evaporation source for Si was used. After cleaning Czochralski n-Si(111) ($\rho=0.015\ \Omega\cdot\text{cm}$) and n-Si(001) ($\rho=0.07\ \Omega\cdot\text{cm}$) substrates at 850 $^\circ\text{C}$ for 30 min in ultrahigh vacuum, approximately 850- and 350-nm-thick undoped *n*-BaSi₂ epitaxial films were grown on Si(111) and Si(001) substrates,

respectively, by reactive deposition epitaxy (RDE; Ba deposition on hot Si) for BaSi₂ template layers, and subsequent MBE (codeposition of Ba and Si on Si) to form thick BaSi₂ films. Details of the growth procedure have been previously described [7,11]. Finally, approximately 50-nm-thick Sb-doped n⁺-BaSi₂ (~10²⁰ cm⁻³) layer was formed for ohmic contacts [12]. For photoresponse measurements, Cr and Au were evaporated on the surface to form 1.5-mm-spacing stripe-shaped electrodes. The photocurrent flowing in the lateral direction between the electrodes was evaluated by a lock-in technique using a 150 W Xenon lamp (5 mW/cm² at 470 nm) with a 25-cm focal-length single monochromator (Bunkoukeiki SM-1700A). The light intensity was calibrated by a pyroelectric sensor (MELLES GRIOT 13PEM001/J). The crystalline quality of the grown films was characterized by reflection high-energy electron diffraction (RHEED), X-ray diffraction (XRD), and transmission electron microscopy (TEM).

3. Results and discussion

Figure 1 show the RHEED patterns of BaSi₂ films after (a) RDE at 550 °C and (a') MBE at 600 °C on Si(111), and after (b) RDE at 530 °C and (b') MBE at 580 °C on Si(001) substrates. The RHEED patterns were observed along the Si[11-2]

and Si[110], respectively. We can see clear streaky RHEED patterns for BaSi₂ films on Si(111), which is typical for *a*-axis-oriented BaSi₂ epitaxial films [13]. On the other hand, two clear sets of streaky patterns with different spacings are seen for BaSi₂ on Si(001), in Figs. 1(b) and 1(b'). The ratio of wide streaky spacing to narrow spacing is approximately 1.7, which is explained by the ratio of $1/b$ to $1/c$. Taking into account that the electron beam was incident along the Si[110] azimuth, these two streaky patterns with different spacings indicate the existence of two epitaxial variants rotating 90° to each other in the surface normal; BaSi₂(100)//Si(001) with BaSi₂[010]//Si[110] and BaSi₂[001]//Si[110] [11].

Figures 2(a) and 2(b) present the θ - 2θ XRD patterns of BaSi₂ films on Si(111) and Si(001) substrates, respectively. The diffraction peaks at $2\theta = 20^\circ, 41^\circ, 63^\circ$ correspond to BaSi₂(200), (400), and (600) planes, respectively, indicating that highly *a*-axis-oriented BaSi₂ films were grown.

Figures 3(a) and 3(b) shows the plan-view bright-field (BF) TEM images of BaSi₂ films on (a) Si(111) and (b) Si(001) substrates. The incident electron beam was almost parallel to the BaSi₂[100] zone axis, but was slightly tilted for the grain boundaries (GBs) to be seen clearly. We can easily see that the grain size of the BaSi₂ film on Si(111) is approximately 0.2 μm . In contrast, the grains of more than 1 μm in

diameters exist in the BaSi₂ film on Si(001) in Fig. 3(b). We speculate that the large grain of BaSi₂ on Si(001) is partly due to the reduced number of epitaxial variants from three for BaSi₂ on Si(111) to two for BaSi₂ on Si(001). However, the difference in grain size is significantly larger than expected. Thus, further studies are required to clarify the mechanism that explains this difference.

Figures 4(a) and 4(b) show the photoresponse spectra measured at RT under various bias voltages applied between the 1.5-mm-spacing stripe-shaped Au/Cr electrodes on the surface of BaSi₂ films on (a) Si(111) and (b) Si(001) substrates. In both samples, photocurrents increased sharply with increasing bias voltages V_{bias} for photon energies greater than the band gap. However, the magnitude of photoresponsivity differed significantly between them. The photoresponsivity reached 13 mA/W at 1.6 eV for BaSi₂ on Si(111) when V_{bias} was 2.5 V on Si(111), while it marked approximately 100 mA/W for BaSi₂ on Si(001). This difference is attributed to the difference in the grain size of BaSi₂ films. It should be noted that in the photoresponse spectra, peaks become pronounced at 1.46 eV. This is due to the non-linear property of the photocurrent caused by the intense line-shaped spectrum of the Xenon light at this photon energy. On the basis of these results, we concluded that the further improvement of photoresponsivity in BaSi₂ epitaxial films is

expected with much larger grains. In this sense, a Si(001) face is more preferable for BaSi₂ than a Si(111) surface.

4. **Summary**

Approximately 900- and 400-nm-thick BaSi₂ epitaxial films were grown on Si(111) and Si(001) substrates, respectively, by MBE. Plan-view BF TEM images revealed that the grain size of BaSi₂ on Si(001) was more than 1 μm, while that on Si(111) was approximately 0.2 μm. When the bias voltage V_{bias} was 2.5 V, the photoresponsivity reached 100 mA/W for BaSi₂ on Si(001) at 1.6 eV. On the other hand, it was only 13 mA/W for BaSi₂ on Si(111).
